Abstract: This is a rare case report of apexification in an immature permanent mandibular first molar. Calcium hydroxide was used for apical root closure of both the mesial and distal canals. Root closure occurred after 13 months following which obturation of the tooth was completed.

Keywords: Molar apexification, Calcium hydroxide, Immature permanent molar roots, Pulpdent

APICAL CLOSURE OF IMMATURE MOLAR ROOTS—A RARE CASE REPORT

The treatment of incompletely formed pulless teeth has presented considerable problems. These teeth have wide open apaxes and the walls of the root canal diverge toward the apical tissues. Mechanical preparation cannot be done in the normal manner because of the large initial size and the flare of the apical part of the canal. A mechanical stop cannot be produced at the apex of the canal and, therefore, control of root filling materials is difficult. Pulless teeth with open apaxes sometimes have been treated by cleaning the canal, overfilling with a standard root filling material, and then performing a modified root resection. This stops root formation, and the result is a short, weak tooth with a doubtful prognosis.1

Apical root closure may result from apexification or bridge formation and is indicated when the pulps of young permanent teeth become necrotic. Various techniques were used to induce the apexification process. Cooke and Rowbotham2 reported a ten-year follow up of incompletely formed pulless teeth that they had treated by dressing the canals with tricresol and formalin. The canals were subsequently filled with a paste of zinc oxide and eugenol containing iodoform and thymol. They were able to show radiographically that further root formation had occurred after the root treatment.

Kaiser3 obtained apexification with calcium hydroxide paste. Frank4 and Heithersay5 obtained successful results when calcium hydroxide in various forms was introduced in canals of immature teeth. Cvek6 examined the results of treating 55 maxillary incisors with immature roots, complete pulpal necrosis, and radiographically demonstrable periaical tissue changes. After antibiotic treatment the canals were filled temporarily with calcium hydroxide. Radiographic bone healing and apical closure were noted in 50 teeth. Steiner and Van Hassel7 did histological studies and reported the formation of cementum like hard tissue after treatment with calcium hydroxide combined with camphorated monochlorophenol. Dylewski8 stated that the calcified material that forms at the apex resembles osteodentin. Mineral trioxide aggregate, a newer material is a suitable replacement for calcium hydroxide for the apexification in immature roots.9 Recently a new technique was introduced...
wherein revascularization of the necrotic infected pulp space of an immature permanent maxillary central incisor was induced in-vivo by stimulation of blood clot from the periapical tissues into the canal space.\textsuperscript{10}

Pulpdent root canal sealer is an ADA accepted permanent root canal filling material. It can be used in both primary and permanent teeth. It is tissue compatible, bacteriostatic, radiopaque and insoluble in the root canal. It sets in two to three hours and it does not shrink upon setting ensuring a positive seal. In the early 1960s, Greenberg and Katz\textsuperscript{11} designed the endodontic pressure syringe, which was manufactured by the Pulpdent Corporation. It is a simple and accurate method of obturating the root canal space. It eliminates voids and also the problems associated with inaccessibility of some posterior teeth having narrow or tortuous canals.

Apexification procedures are most often undertaken in immature permanent anterior teeth where as few case reports in premolars\textsuperscript{12} and primary anterior teeth\textsuperscript{13} are also present. A PUBMED and a MEDLINE search did not reveal any case of apexification of immature permanent molar. Rotstein, Friedman and Katz\textsuperscript{14} reported 2 cases in which calcium hydroxide induced apical root closure in posterior mature teeth where the apical constriction was lost because of chronic inflammatory process. Weine\textsuperscript{15} reported apexification in the palatal root of a maxillary molar where previous caries followed by failed vital pulp therapy left the palatal root undeveloped. Hence this is a rare case report of an apexification in immature mandibular permanent molar.

**Case Report**

A 10-year-old boy reported to the department with the chief complaint of intermittent pain in the lower left posterior tooth region which was of one month duration. Past medical and past dental history was non-contributory. Clinical examination revealed dental caries in left mandibular first permanent molar (tooth #19). The tooth was found to be tender on percussion. Radiographic examination revealed dental caries in left mandibular first permanent molar (tooth #19). The tooth was found to be tender on percussion. Radiographic examination revealed periapical radiolucency in relation to incompletely formed mesial and distal root apices in tooth #19 (Fig. 1). After isolation, access opening was done and the necrotic pulp tissue was removed with a large barbed broach. Working length was determined slightly short of the radiographic apex. Instrumentation was performed with a gentle circumferential filling motion, aided by copious irrigation with saline. Large sterile paper points were used to dry the canals. The canals were filled with calcium hydroxide paste in a premixed syringe (Calcicur–Voco-Cuxhaven-Germany). The tooth was then temporarily restored with glass ionomer cement. Immediate post operative radiograph was taken which confirmed the presence of calcium hydroxide paste in the canals. Patient was asked to report after three months for review but patient returned only after ten months. Radiographic examination revealed resolved periapical radiolucency and satisfactory apical closure in one of the mesial canal. The other mesial canal and the distal canal did not have satisfactory apical closure (Fig. 2). Hence apexification procedure was repeated by placing calcium hydroxide paste as previously mentioned (Fig 3). A hard apical barrier was detected radiographically with tactile sensation using a 15 size K file after 3 months. Working length was determined and cleaning and shaping of the canals were done upto 40 size using K files. Obturation was accomplished with pulpdent root canal sealer using endodontic pressure syringe. Access cavity was restored with glass ionomer cement (Fig. 4). Post endodontic restoration was done.

**Discussion**

The most important factors for apexification are canal cleaning, in other words removal of all necrotic tissue, and the temporary hermetic sealing of the tooth to avoid bacterial infiltration. Diverse materials have been proposed to induce the apexification of nonvital permanent teeth such as zinc...
oxide- iodoform, polyantibiotic paste, Walkhoff’s antiseptic paste, calcium hydroxide based materials, resorbable tricalcium phosphate, Vitapex, or without any inducement material at all. The most commonly advocated medicament is calcium hydroxide, although recently considerable interest has been expressed in the use of MTA.

The biological and bacteriological actions of calcium hydroxide, which was introduced in dentistry by Hermann in 1930, confirm its preference for intracanal use. Kaiser and Frank were the first to use it for reliable closure of immature roots. Since then, root closure of pulless permanent teeth with calcium hydroxide has become an accepted procedure and is well documented in literature. Morse et al studied 5 treatment methods for teeth with incomplete root formation and pulpal necrosis and concluded that the success of therapy with apical tissue repair is due to the antibacterial action and the calcification-inducing action of calcium hydroxide. Selden reported an unexpected apexification outcome with calcium hydroxide in permanent mandibular cuspid. Following apexification, the root end morphologically closely resembled normal root end formation despite the evidence of total pulpal necrosis and infection. According to Sheehy and Roberts the use of calcium hydroxide for apical barrier formation is successful in 74-100% of cases irrespective of the proprietary brand used. Hence in our case we decided to use calcium hydroxide paste for apexification.

Apical hard tissue barrier induced by either apexification or apexogenesis is usually irregular and porous and may take the form of a cap or a bridge. Histologically, its characteristics may be of dentin, cementum or osteodentin. Its formation may take 3 to 24 months. Gupta, Sharma and Dang conducted a single visit apexification in a non-vital and immature mandibular premolar and concluded that frequent changing of the calcium hydroxide dressing is not always required to induce apical closure. In our case a barrier was found to be formed at 13 months following apexification.

INSTRUCTIONS TO AUTHORS

JAYPEE’S INTERNATIONAL JOURNAL OF CLINICAL PEDIATRIC DENTISTRY is an international journal, the aim of which is to promote education and research in pediatric dentistry. The journal publishes papers on all the aspects of pediatric dentistry. Manuscripts prepared according to “Uniform Requirements of Biomedical Journal” are invited for editorial review and publication. Published papers are the views of the respective authors and do not necessarily represent the views of the editorial board or publishing house.

Manuscript submission: Manuscript are received with the understanding that they contain original data that is not previously published or is being considered for publication elsewhere. Only individuals who have made significant contributions to the manuscript should be listed as authors, all other contributions should be noted in acknowledgments. Authors are required to submit two printed copies of the manuscript including all tables and figures (photographs) along with a CD, which should contain both blinded and unblinded article file and introduction file in Microsoft word format and photographs in jpeg, tiff, gif, bmp, eps format. The first or corresponding author should send the following duly signed by all contributing authors along with the manuscript: contribution form, copyright transfer form, corresponding author form and submission form. Send the manuscripts to Editor-in-Chief:
Dr Usha Mohan Das
Dean, VS Dental College, Bangalore
e-mail: ushymohandas@gmail.com

Online submission: You can also submit your manuscripts online by e-mail to: ushymohandas@gmail.com, jijcpd@gmail.com or upload your manuscript at www.jaypeebrothers.com (Please note only one mode of submission must be used, i.e. postal or online. For online submission send 1 hard copy of the photographs along with contribution form, copyright transfer form, corresponding author form and submission form to the above address.

Type of articles: The journal publishes original articles not exceeding 2500 words and case reports not exceeding 1000 words (excluding introduction file, abstract, legends and references) with not more than 15 references.

Preparation of manuscript: Manuscript should be prepared in text file and separate file for illustrations. Times new roman or Arial font with a font size of 12 and double spaced text with one inch margins should be the basis of text files.

Introduction file should contain a covering letter, acknowledgment and title page (type of manuscript, title of manuscript, complete address, degree and academic details of all authors including phone numbers and e-mail. The details of corresponding author must be mentioned separately).

Abstract: All manuscripts must have an abstract, which provides the reader with a brief but complete summary of the paper. The aim, material and method, results and conclusion must be clearly demarcated. The abstract should not be more than 250 words for an original article and 150 words for a case report. A list of key words must be included at the end of abstract.

Introduction: It should provide a concise summary of the research and state the hypothesis to be tested.

Material & methods: All relevant attributes of the material forming the subject of the research should be provided. Experimental methodology should be concisely and appropriately explained. Commercially produced materials, devices, software, etc. must be followed by name of manufacturer and location. If an abbreviation has to be used then it should be placed in parentheses following the full spelling of the term for the first time. Statistical methods should be clearly specified. Manuscripts reporting human studies should include evidence that study was ethically conducted in accordance with declaration of Helsinki.

Results should be presented sequentially in tables and illustrations. The data in the tables and illustration should not be repeated in text but should indicate the most important result and describe relevant pattern. All units of measure should be in accordance with International system of units. Laboratory data values should be rounded to the number of digits that reflects precision. The statistical comparisons should include statistical test value and p-value. If P > .01, the actual p-value must be expressed in two digits. If P<.01 it should be expressed in three digits and non-significant values should be mentioned as NS.

Discussion: This section describes the findings of the study, limitations of materials, interpreting the data and drawing contribution of the study in scientific field. No repetitions of the previous sections should be done. All the controversies, implications and future prospects related to the study should be mentioned. Discussion should end with a brief summary of conclusion.

Legends should have detailed explanation of the illustrations.

Tables: Each table should be double-spaced typed on separate page and should be numbered in Arabic numericals. Short headings should appear at the top of each column. All non-standard abbreviations should be explained.
Figures / Illustrations: Colored photos with minimum 300 dpi resolution of 4 X 6 inch should be sent. Labels citing the legend, figure no., author and title of the manuscript should be pasted on back of photograph.

Acknowledgements: Funding and other sources of support must be disclosed in this section. Personal acknowledgment should be limited to professionals who have contributed to the paper but whose contribution does not justify authorship.

References should be relevant to the material presented and identified by superscript in Arabic numerals. List of references should appear at the end of paper as they appear in numeric order as they are cited in text and the abbreviations used should be those used by Index Medicus. Authors should verify accuracy of all references and provide direct references whenever possible. Avoid using abstracts or in press papers for references.
